Outline

- OpenMP: History and high level overview
- Software development with OpenMP
- OpenMP 2.5: other essential constructs
  - Synchronization
  - Runtime library
  - Loop scheduling
- OpenMP memory model ← beware the flush
- OpenMP 3.0
- The NUMA crisis and OpenMP
OpenMP: An API for Writing Multithreaded Applications

- A set of compiler directives and library routines for parallel application programmers
- Makes writing multi-threaded applications in Fortran, C and C++ as easy as we can make it.
- Standardizes last 20 years of SMP practice

* The name “OpenMP” is the property of the OpenMP Architecture Review Board.
OpenMP pre-history

- OpenMP based upon SMP directive standardization efforts ... PCF and aborted ANSI X3H5 – late 80’s
  - Nobody fully implemented either standard
  - Only a couple of partial implementations

- Vendors considered proprietary API’s to be a competitive feature:
  - Every vendor had proprietary directives sets
  - Even KAP, a “portable” multi-platform parallelization tool used different directives on each platform

PCF – Parallel Computing Forum
SMP – Symmetric multiprocessor
KAP – parallelization tool from KAI.
API – application programming interface
History of OpenMP

- SGI: Merged, needed commonality across products
- Cray
- KAI: ISV - needed larger market
- ASCI: was tired of recoding for SMPs. Urged vendors to standardize.

Wrote a rough draft straw man SMP API
Other vendors invited to join

OpenMP Execution Model:

- **Master thread** spawns a **team of threads** as needed.
- Parallelism added incrementally until performance are met: i.e. the sequential program evolves into a parallel program.
The essence of OpenMP

- Create threads that execute in a shared address space:
  - The only way to create threads is with the "parallel construct"
  - Once created, all threads execute the code inside the construct.

- Split up the work between threads by one of two means:
  - SPMD (Single program Multiple Data) ... all threads execute the same code and you use the thread ID to assign work to a thread.
  - Workshare constructs split up loops and tasks between threads.

- Manage data environment to avoid data access conflicts
  - Synchronization so correct results are produced regardless of how threads are scheduled.
  - Carefully manage which data can be private (local to each thread) and shared.
Example Problem: Numerical Integration

Mathematically, we know that:

\[
\int_{0}^{1} \frac{4.0}{1 + x^2} \, dx = \pi
\]

We can approximate the integral as a sum of rectangles:

\[
\sum_{i=0}^{N} F(x_i) \Delta x \approx \pi
\]

Where each rectangle has width \( \Delta x \) and height \( F(x_i) \) at the middle of interval \( i \).
static long num_steps = 100000;
double step;
void main ()
{
    int i;  double x, pi, sum = 0.0;

    step = 1.0/(double) num_steps;
x = 0.5 * step;
for (i=0;i<= num_steps; i++){
    x+=step;
    sum += 4.0/(1.0+x*x);
}
pi = step * sum;
}
# How to write a parallel program

## Stages of parallel programming

PI Program: identify Concurrency

```c
static long num_steps = 100000;
double step;
void main ()
{
    int i; double x, pi, sum = 0.0;
    step = 1.0/(double) num_steps;
    x = 0.5 * step;
    for (i=0;i<= num_steps; i++){
        x+=step;
        sum += 4.0/(1.0+x*x);
    }
    pi = step * sum;
}
```

Loop iterations can in principle be executed concurrently.
static long num_steps = 100000;
double step;
void main ()
{
    double pi, sum = 0.0;
    step = 1.0/(double) num_steps;

    int i; double x;
    for (i=0; i<= num_steps; i++) {
        x = (i+0.5)*step;
        sum += 4.0/(1.0+x*x);
    }

    pi = step * sum;
}
static long num_steps = 100000;
#define NUM 4  //expected max thread count
double step;
void main ()
{
    double pi, sum[NUM] = {0.0};
    step = 1.0/(double) num_steps;

    int i, ID=0;   double x;
    for (i=0;i<= num_steps; i++){
        x = (i+0.5)*step;
        sum[ID] += 4.0/(1.0+x*x);
    }

    for(int i=0, pi=0.0;i<NUM;i++)
        pi += step * sum[i];

    Common Trick: promote scalar “sum” to an array indexed by the number of threads to create thread local copies of shared data.
PI Program: Express Concurrency using OpenMP

```c
#include <omp.h>
static long num_steps = 100000;
#define NUM 4
double step;
void main ()
{
    double pi, sum[NUM] = {0.0};
    step = 1.0/(double) num_steps;
    #pragma omp parallel num_threads(NUM)
    {
        int i, ID;
        double x;
        ID = omp_get_thread_num();
        for (i=ID;i<= num_steps; i+=NUM){
            x = (i+0.5)*step;
            sum[ID] += 4.0/(1.0+x*x);
        }
        for(int i=0, pi=0.0;i<NUM;i++)
            pi += step * sum[i];
    }
}
```

Variables defined inside a thread are private to that thread.

Automatic variables defined outside a parallel region are shared between threads.

Create NUM threads

Each thread executes code in the parallel block

Simple mod to loop to deal out iterations to threads.
PI Program: Fixing the NUM threads bug

```c
#include <omp.h>
static long num_steps = 100000;
#define NUM 4
double step;
void main () {
    double pi, sum[NUM] = {0.0};
    step = 1.0/(double) num_steps;
    #pragma omp parallel num_threads(NUM)
    {
        int nthreads = omp_get_num_threads();
        int i, ID);
        ID = omp_get_thread_num();
        for (i=ID;i<= num_steps; i+=nthreads){
            x = (i+0.5)*step;
            sum[ID] += 4.0/(1.0+x*x);
        }
    }
    for(int i=0, pi=0.0;i<NUM;i++)
        pi += step * sum[i];
}
```

NUM is a requested number of threads, but an OS can choose to give you fewer.

Hence, you need to add a bit of code to get the actual number of threads.
Incremental Parallelism

- Software development with incremental Parallelism:
  - Behavior preserving transformations to expose concurrency.
  - Express concurrency incrementally by adding OpenMP directives... in a large program I can do this loop by loop to evolve my original program into a parallel OpenMP program.
  - Build and time program, optimize as needed with behavior preserving transformations until you reach the desired performance.
PI Program: Execute Concurrency
#include <omp.h>
static long num_steps = 100000;
#define NUM 4
double step;
void main ()
{
    double pi, sum[NUM] = {0.0};
    step = 1.0/(double) num_steps;
#pragma omp parallel num_threads(NUM)
{
    int nthreads = omp_get_num_threads();
    int i, ID; double x;
    ID = omp_get_thread_num();
    for (i=ID;i<= num_steps; i+=nthreads){
        x = (i+0.5)*step;
        sum[ID] += 4.0/(1.0+x*x);
    }
}

    for(int i=0, pi=0.0;i<NUM;i++)
    pi += step * sum[i];
}
PI Program: Safe update of shared data

```
#include <omp.h>
static long num_steps = 100000;
define NUM 4

double step;

void main ()
{
    double pi, sum=0.0;
    step = 1.0/(double) num_steps;

#pragma omp parallel num_threads(NUM)
{
    int i, ID;
    double x, psum = 0.0;
    ID = omp_get_thread_num();
    ID = omp_get_thread_num();
    for (i=ID;i<= num_steps; i+=nthreads){
        x = (i+0.5)*step;
        psum += 4.0/(1.0+x*x);
    }

#pragma omp critical
    sum += psum
}

pi = step * sum;
```
Pi program: making loop-splitting and reductions even easier

```c
#include <omp.h>
static long num_steps = 100000; double step;
void main ()
{  int i;  double x, pi, sum = 0.0;
   step = 1.0/(double) num_steps;
#pragma omp parallel for private(i, x) reduction(+:sum)
   for (i=0;i<= num_steps; i++){
      x = (i+0.5)*step;
      sum = sum + 4.0/(1.0+x*x);
   }
   pi = step * sum;
}
```

Private clause creates data local to a thread

Reduction used to manage dependencies
Outline

• OpenMP: History and high level overview
• Software development with OpenMP
• OpenMP 2.5: other essential constructs
  - Synchronization
  - Runtime library
  - Loop scheduling
• OpenMP memory model ⇐ beware the flush
• OpenMP 3.0
• The NUMA crisis and OpenMP
**Synchronization: Barrier**

- **Barrier**: Each thread waits until all threads arrive.

```c
#pragma omp parallel shared (A, B, C) private(id)
{
    id=omp_get_thread_num();
    A[id] = big_calc1(id);
    #pragma omp barrier
    #pragma omp for
    for(i=0;i<N;i++){C[i]=big_calc3(i,A);}
    #pragma omp for nowait
    for(i=0;i<N;i++){ B[i]=big_calc2(C, i); }
    A[id] = big_calc4(id);
}
```

- Implicit barrier at the end of a parallel region.
- Implicit barrier at the end of a for worksharing construct.
- No implicit barrier due to `nowait`.

Putting the master thread to work

- The **master** construct denotes a structured block that is only executed by the master thread. The other threads just skip it (no synchronization is implied).

```c
#pragma omp parallel
{
    do_many_things();
#pragma omp master
    { exchange_boundaries(); }
#pragma omp barrier
    do_many_other_things();
}
```
### Runtime Library routines and ICVs

- To use a known, fixed number of threads in a program, (1) tell the system that you don’t want dynamic adjustment of the number of threads, (2) set the number of threads, then (3) save the number you got.

```
#include <omp.h>
void main()
{
  int num_threads;
  omp_set_dynamic( 0 );
  omp_set_num_threads( omp_num_procs() );

  #pragma omp parallel
  {
    int id=omp_get_thread_num();
    #pragma omp single
    num_threads = omp_get_num_threads();
    do_lots_of_stuff(id);
  }
}
```

- Internal Control Variables (ICVs) … define state of runtime system to a thread. Consistent pattern: set with “omp_set” or an environment variable, read with “omp_get”
Optimizing loop parallel programs

```c
#include <omp.h>
#pragma omp parallel
{
    // define neighborhood as the num_neighbors particles
    // within “cutoff” of each particle “i”.
    #pragma omp for
    for( int i = 0; i < n; i++ )
    {
        Fx[i]=0.0; Fy[i]=0.0;
        for (int j = 0; j < num_neigh[i]; j++)
            neigh_ind = neigh[i][j];
        Fx[i] += forceX(i, neigh_ind);
        FY[i] += forceY(i, neigh_ind);
    }
}
```

Particles may be unevenly distributed ... i.e. different particles have different numbers of neighbors.

Evenly spreading out loop iterations may fail to balance the load among threads.

We need a way to tell the compiler how to best distribute the load.
The schedule clause

- The schedule clause affects how loop iterations are mapped onto threads
  - `schedule(static [,chunk])`
    - Deal-out blocks of iterations of size “chunk” to each thread.
  - `schedule(dynamic[,chunk])`
    - Each thread grabs “chunk” iterations off a queue until all iterations have been handled.
  - `schedule(guided[,chunk])`
    - Threads dynamically grab blocks of iterations. The size of the block starts large and shrinks down to size “chunk” as the calculation proceeds.
  - `schedule(runtime)`
    - Schedule and chunk size taken from the OMP_SCHEDULE environment variable (or the runtime library … for OpenMP 3.0).
#include <omp.h>
#pragma omp parallel
{
    // define neighborhood as the num_neigh particles
    // within “cutoff” of each particle “i”.
    #pragma omp for schedule(dynamic, 10)
        for(int i = 0; i < n; i++)
        {
            Fx[i]=0.0; Fy[i]=0.0;
            for(int j = 0; j < num_neigh[i]; j++)
            {
                neigh_ind = neigh[i][j];
                Fx[i] += forceX(i, neigh_ind);
                FY[i] += forceY(i, neigh_ind);
            }
        }
}
## Loop work-sharing constructs:
### The schedule clause

<table>
<thead>
<tr>
<th>Schedule Clause</th>
<th>When To Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>STATIC</td>
<td>Pre-determined and predictable by the programmer</td>
</tr>
<tr>
<td>DYNAMIC</td>
<td>Unpredictable, highly variable work per iteration</td>
</tr>
<tr>
<td>GUIDED</td>
<td>Special case of dynamic to reduce scheduling overhead</td>
</tr>
</tbody>
</table>

**Least work at runtime:** scheduling done at compile-time

**Most work at runtime:** complex scheduling logic used at run-time
Summary of OpenMP's key constructs

• The only way to create threads is with the parallel construct:
  
  \#pragma omp parallel

• All thread execute the instructions in a parallel construct.

• Split work between threads by:
  - SPMD: use thread ID to control execution
  - Worksharing constructs to split loops (simple loops only)
    \#pragma omp for

• Combined parallel/workshare as a shorthand
  \#pragma omp parallel for

• High level synchronization is safest
  \#pragma critical
  \#pragma barrier
Outline

• OpenMP: History and high level overview
• Software development with OpenMP
• OpenMP 2.5: other essential constructs
  - Synchronization
  - Runtime library
  - Loop scheduling
• OpenMP memory model ← beware the flush
• OpenMP 3.0
• The NUMA crisis and OpenMP
There is a single address space (shared memory) but due to the caches, a processor may hold a value for "x" that is different from the one in shared memory.
OpenMP Memory Model: Basic Terms

Program order:

Source code:

\[ W_a \ W_b \ R_a \ R_b \ldots \]

Compiler:

Executable code:

\[ W_b \ R_b \ W_a \ R_a \ldots \]

Thread:

Private view:

\[ \text{threadprivate} \]

Memory:

\[ a \quad b \]

Commit order:

RW’s in any semantically equivalent order
OpenMP: Forcing a consistent view of memory

- The **flush** construct denotes a sequence point where a thread tries to create a consistent view of memory for all thread-visible variables (the “flush set”).
  
  ```c
  #pragma omp flush
  ```

- For the variables in the flush set:
  - All memory operations (both reads and writes) defined prior to the sequence point must complete.
  - All memory operations (both reads and writes) defined after the sequence point must follow the flush.
  - Variables in registers or write buffers must be updated in memory.

- Compilers reorder instructions to better exploit the functional units and keep the machine busy
  - A compiler CANNOT do the following:
    - Reorder read/writes of variables in a flush set relative to a flush.
    - Reorder flush constructs when flush sets overlap.
  - A compiler CAN do the following:
    - Reorder instructions NOT involving variables in the flush set relative to the flush.
    - Reorder flush constructs that don’t have overlapping flush sets.

---

OpenMP applies flushes automatically at the “right” places (barriers, end of workshare constructs, etc). You usually don’t need to worry about flushes explicitly.
Pair-wise synchronization in OpenMP

- OpenMP lacks synchronization constructs that work between pairs of threads.
- When this is needed you have to build it yourself.
- Pair wise synchronization
  - Use a shared flag variable
  - Reader spins waiting for the new flag value
  - Use flushes to force updates to and from memory

This use of flush exposes the details of OpenMP’s relaxed memory model … a risky practice for experienced shared memory programmers only.
# Producer/consumer and flush

```c
int main()
{
    double *A, sum, runtime;  int numthreads, flag = 0;
    A = (double *)malloc(N*sizeof(double));

    #pragma omp parallel sections
    {
        #pragma omp section
        {
            fill_rand(N, A);
            #pragma omp flush
            flag = 1;
            #pragma omp flush
        }
        #pragma omp section
        {
            #pragma omp flush
            while (flag != 1){
                #pragma omp flush
            }
            #pragma omp flush
            sum = Sum_array(N, A);
        }
    }
}
```

Use flag to Signal when the “produced” value is ready

Flush forces refresh to memory. Guarantees that the other thread sees the new value of A

Flush needed on both “reader” and “writer” sides of the communication

Notice you must put the flush inside the while loop to make sure the updated flag variable is seen
The rest of OpenMP 2.5

- Create threads
  - parallel
- Share work among a set of threads
  - for
  - single
  - Sections
- Synchronize to remove race conditions
  - Critical
  - Atomic
  - Barrier
  - locks
  - flush

- Manage data environment
  - Private
  - shared
  - threadprivate
  - firstprivate
  - Lastprivate
  - Reduction

- Interact with runtime
  - change numbers of threads
  - Discover thread properties
  - modify environment
Outline

• OpenMP: History and high level overview
• Software development with OpenMP
• OpenMP 2.5: other essential constructs
  - Synchronization
  - Runtime library
  - Loop scheduling
• OpenMP memory model ← beware the flush
• OpenMP 3.0
• The NUMA crisis and OpenMP
OpenMP 3.0: completed May 2008

- Task expression
  - Task Queues
  - Loop collapse

- Resource management
  - Stack size control
  - Thread wait policy
  - Improved Nesting support
  - Multiple Internal control variables

- Scheduling
  - STATIC schedule
  - Schedule kinds

- Clean up:
  - Constructors/destructors
  - Memory model
  - Unsigned int in a for-loop
  - Storage reuse

Of all these changes, the most significant by far is the addition of task queues
Tasks beyond loops

• OpenMP is fundamentally based on tasks ... i.e. the constructs in OpenMP define sets of tasks executed by teams of threads.

• OpenMP 2.5 provides only a few ways to define tasks:
  - The code redundantly executed inside parallel regions (SPMD programs).
  - Iterations from “simple loops” split between threads.
  - Section construct
  - Single construct (with a no wait if you want concurrency)

• OpenMP 3.0 adds explicit tasks with deferred execution (task queues) ... thereby dramatically expanding the scope of algorithms that can be handled by OpenMP
Explicit Tasks in OpenMP 3.0

- OpenMP 2.5 cannot handle the very common case of a pointer chasing loop:

```c
nodeptr list, p;
for (p=list; p!=NULL; p=p->next)
    process(p->data);
```

- OpenMP 3.0 covers this case with explicit tasks:

```c
nodeptr list, p;
#pragma omp single
{
    for (p=list; p!=NULL; p=p->next)
        #pragma omp task firstprivate(p)
            process(p->data);
}
```

One thread goes through the loop and creates a set of tasks. Captures value of p for each task. Tasks go on a queue to be executed by an available thread.
Task Expression:
The new OpenMP 3.0 Task directive

• Explicit tasks are created with the task construct
  
  #pragma omp task [<clause>] ...
  <structured block>

• A task is executed by a thread, called the task-thread, which may be any thread in the encountering thread’s team.

• A task barrier ... is a point where preceding tasks must complete before threads continue

• To prevent deadlock, we define “thread switching points” where a thread may pause and execute other tasks.
  
  - This happens most commonly at barriers or other natural places where a break in the action makes sense.
Tasks with synchronization

```c
struct node {
    struct node *left;
    struct node *right;
};
extern void process(struct node *);
void postorder_traverse( struct node *p ) {
    if (p->left)
        #pragma omp task // p is firstprivate by default
        postorder_traverse(p->left);
    if (p->right)
        #pragma omp task // p is firstprivate by default
        postorder_traverse(p->right);
    #pragma omp taskwait
    process(p);
}
```

Do not proceed until prior tasks in scope have completed
Outline

• OpenMP: History and high level overview
• Software development with OpenMP
• OpenMP 2.5: other essential constructs
  - Synchronization
  - Runtime library
  - Loop scheduling
• OpenMP memory model ← beware the flush
• OpenMP 3.0
• The NUMA crisis and OpenMP
OpenMP Computational model

- OpenMP was created with a particular abstract machine or *computational model* in mind:
  - Multiple processing elements.
  - A shared address space with “equal-time” access for each processor.
  - Multiple light weight processes (threads) managed outside of OpenMP (the OS or some other “third party”).
How realistic is this model?

- Some of the old supercomputer mainframes followed this model,

- But as soon as we added caches to CPUs, the SMP model implied by OpenMP fell apart.
  - Caches ... all memory is equal, but some memory is more equal than others.

A CPU with lots of cache ...
Memory Hierarchies

- A typical microprocessor memory hierarchy

- Instruction cache and data cache pull data from a unified cache that maps onto RAM.
- TLB implements virtual memory and brings in pages to support large memory footprints.
Do you need to worry about the TLB?

Transpose: 2 threads on a Dual Proc Xeon

Time (secs) vs Matrix Order

Ignore TLB issues (no tiling)

Tiled to optimize use of TLB

Source: M Frumkin, R. van de Wijngaart, T. G. Mattson, Intel
Put these into a larger system and it only gets worse

• Consider a typical NUMA computer:

![Diagram of a NUMA computer with nodes NODE 0 and NODE 1, processors Proc0, Proc1, Proc2, and Proc3, and memories Memory (0) and Memory (1).]

• Memory access takes longer if memory is remote.
• For example, on an SGI Altix:
  • Proc0 to local memory (0) 207 cycles
  • Proc0 to remote memory (1) 409 cycles

Consider a cluster, and it gets much worse!

<table>
<thead>

Surviving NUMA: initializing data

- Keep data close to where it is needed:
  - Bind threads to cores.
  - Initialize the data so its near the core that will use it.
- Hardware: a 4-socket machine with dualcore Opteron processors with processor binding enabled.

Conclusion

• OpenMP is one of the most commonly used APIs for programming shared memory computers:
  - My friends in the Intel Software group tell me countless ISVs are shipping applications using OpenMP.

• Incremental parallelism with testing at every step is not a luxury ... it is a requirement.

• OpenMP makes things about as easy as we can for application programmers.

• OpenMP is useful in hybrid models to help expose additional levels of concurrency

• BUT, OpenMP is in trouble when it comes to NUMA machines ... and practically all machines are NUMA so this is a big deal.
